RESUMEN

Se da la fotometría de setenta estrellas RR Lyrae seleccionadas de la lista de van Herk. Se obtuvieron magnitudes y colores durante máximo y mínimo de sesenta y cuatro estrellas. Para una estrella se dan los valores sólo durante el mínimo. Para las cinco faltantes, las observaciones fueron insuficientes para determinar máximos y mínimos. En la Tabla 4 se listan magnitudes y colores promedio de ciento setenta y cuatro estrellas bien observadas. Estos promedios corresponden a máximo y mínimo.

ABSTRACT

Photoelectric UBV observations are given for 70 RR Lyrae stars selected from van Herk's list of field variables with known proper motion or radial velocity. Magnitudes and colors at maximum and minimum light were obtained for 64 stars, while only minimum light values were observed for one star. For the remaining five stars the observations were insufficient to determine either light extreme. In Table 4 are listed the mean colors and magnitudes at light extreme for all the 174 stars adequately observed during the course of this program.

Key words: PHOTOMETRY — VARIABLE STARS.

I. INTRODUCTION

At the suggestion of Professor J. Oort of Leiden Observatory, we undertook, starting in the fall of 1963, to obtain photoelectric UBV magnitudes and colors at minimum and maximum light of all the brighter RR Lyrae stars selected, from a list provided by Dr. van Herk, as being accessible to us in Tucson. The measures obtained in the first portion of the program have already been published (Fitch, Wiśniewski and Johnson 1966; hereinafter referred to as Paper I). Observations on the concluding portion of the program were obtained up to the spring of 1970 and are reported here.

II. THE OBSERVATIONS

The equipment and observing procedures were essentially the same as described in Paper I. The

observations listed in Table 1 were obtained with the 28-inch and 61-inch telescopes at the Catalina observing stations of LPL by Bookmeyer Lee and Wiśniewski; and the data reductions were carried out in the LPL data-processing center by Messrs. J. Kij and R. I. Mitchell. The measures listed in Table 2 were obtained with the 36-inch telescope at the Kitt Peak observing station of Steward Observatory by Fitch, and processed on the CDC 6400 computer at the University of Arizona Computing Center with programs written by Fitch.

As in Paper I, U, B, and V magnitudes at light extrema were read from smoothed curves through the phase plots of the measures. The resulting colors and magnitudes at individually observed light extremes are given in Table 3, where minima and maxima observed on the same night are listed on

the same line. Finally, Table 4 gives our best estimates, for each of the 174 stars observed during the full course of this program, of V, B-V, and U-B at minimum and maximum light, together with the period P (taken from the GCVS or the Cracow ephemeris), the *observed* rise time $(M-m)/P$, and the *observed* V amplitude ΔV . When two or more observed extrema for one star agreed well, their average value was used in Table 4; but when the amplitude was highly variable, the larger amplitude values were used. As indicated in the last column of Table 4, the RRc-type variable RW Ari was found by Wiśniewski (1972) to also be a member of an eclipsing system.

Data processing for part of this material has been provided by the University of Arizona Computing Center. The total program has been supported in part by the National Science Foundation through grants GP-1653, 6749, and 14413.
